An Implementation of Sin and Cos Using Gal's Accurate Tables

Pascal Leroy (phl)

2025-02-02

This document describes the implementation of functions Sin and Cos in Principia. The goals of that implementation are to be portable (including to machines that do not have a fused multiply-add instruction), achieve good performance, and ensure correct rounding.

Overview

The implementation follows the ideas described by [GB91] and uses accurate tables produced by the method presented in [SZ05]. It guarantees correct rounding with a high probability. In circumstances where it cannot guarantee correct rounding, it falls back to the (slower but correct) implementation provided by the CORE-MATH project [SZG22] [ZSG+24]. More precisely, the algorithm proceeds through the following steps:

- perform argument reduction using Cody and Waite's algorithm in double precision (see [Mul+10, p. 379]);
- if argument reduction loses too many bits (i.e., the argument is close to a multiple of $\frac{\pi}{2}$), fall back to cr_sin or cr_cos;
- otherwise, uses accurate tables and a polynomial approximation to compute Sin or Cos with extra accuracy;
- if the result has a "dangerous rounding configuration" (as defined by [GB91]), fall back to cr_sin or cr_cos;
- otherwise return the rounded result of the preceding computation.

Notation and Accuracy Model

In this document we assume a base-2 floating-point number system with M significand bits¹ similar to the IEEE formats. We define a real function \mathfrak{m} and an integer function \mathfrak{e} denoting the *significand* and *exponent* of a real number, respectively:

$$x = \pm m(x) \times 2^{e(x)}$$
 with $2^{M-1} \le m(x) \le 2^M - 1$

Note that this representation is unique. Furthermore, if x is a floating-point number, $\mathfrak{m}(x)$ is an integer.

The *unit of the last place* of *x* is defined as:

$$u(x) := 2^{e(x)}$$

In particular, $u(1) = 2^{1-M}$ and:

$$\frac{|x|}{2^M} < \frac{|x|}{2^M - 1} \le \mathfrak{u}(x) \le \frac{|x|}{2^{M - 1}} \tag{1}$$

We ignore the exponent bias, overflow and underflow as they play no role in this discussion.

Finally, for error analysis we use the accuracy model of [Higo2], equation (2.4): everywhere they appear, the quantities δ_i represent a roundoff factor such that $|\delta_i| < u = 2^{-M}$ (see pages 37 and 38). We also use θ_n and γ_n with the same meaning as in [Higo2], lemma 3.1.

 $^{^{1}}$ In binary64, M = 53.

Approximation of $\frac{\pi}{2}$

To perform argument reduction, we need to build approximations of $\frac{\pi}{2}$ with extra accuracy and analyse the circumstances under which they may be used and the errors that they entail on the reduced argument.

Let $z \ge 0$. We start by defining the truncation function $\text{Tr}(\kappa, z)$ which clears the last κ bits of the significand of z:

$$\operatorname{Tr}(\kappa, z) := |2^{-\kappa} \operatorname{m}(z)| 2^{\kappa} \operatorname{\mathfrak{u}}(z)$$

We have:

$$z - \text{Tr}(\kappa, z) = (2^{-\kappa} \, \text{m}(z) - [2^{-\kappa} \, \text{m}(z)]) \, 2^{\kappa} \, \mathfrak{u}(z)$$

The definition of the floor function implies that the quantity in parentheses is in [0, 1[and therefore:

$$0 \le z - \operatorname{Tr}(\kappa, z) < 2^{\kappa} \mathfrak{u}(z)$$

Furthermore if the bits that are being truncated start with exactly k zeros we have the stricter inequality:

$$2^{\kappa'-1}\mathfrak{u}(z) \le z - \operatorname{Tr}(\kappa, z) < 2^{\kappa'}\mathfrak{u}(z) \quad \text{with} \quad \kappa' = \kappa - k \tag{2}$$

This leads to the following upper bound for the unit of the last place of the truncation error:

$$\mathfrak{u}(z - \operatorname{Tr}(\kappa, z)) < 2^{\kappa' - M + 1} \mathfrak{u}(z)$$

which can be made more precise by noting that the function $\mathfrak u$ is always a power of 2:

$$\mathfrak{u}(z - \operatorname{Tr}(\kappa, z)) = 2^{\kappa' - M} \mathfrak{u}(z) \tag{3}$$

Two-Term Approximation

In this scheme we approximate $\frac{\pi}{2}$ as the sum of two floating-point numbers:

$$\frac{\pi}{2} \simeq C_1 + \delta C_1$$

which are defined as:

$$\begin{cases} C_1 & \coloneqq \operatorname{Tr}\left(\kappa_1, \frac{\pi}{2}\right) \\ \delta C_1 & \coloneqq \left[\frac{\pi}{2} - C_1 \right] \end{cases}$$

Equation (2) applied to the definition of C_1 yields:

$$2^{\kappa_1'-1} \mathfrak{u}\left(\frac{\pi}{2}\right) \le \frac{\pi}{2} - C_1 < 2^{\kappa_1'} \mathfrak{u}\left(\frac{\pi}{2}\right)$$

where $\kappa_1' \leq \kappa_1$ accounts for any leading zeroes in the bits of $\frac{\pi}{2}$ that are being truncated. Accordingly equation (3) yields, for the unit of the last place:

$$\mathfrak{u}\left(\frac{\pi}{2}-C_1\right)=2^{\kappa_1'-M}\,\mathfrak{u}\left(\frac{\pi}{2}\right)$$

Noting that the absolute error on the rounding that appears in the definition of δC_1 is bounded by $\frac{1}{2} u \left(\frac{\pi}{2} - C_1 \right)$, we obtain the absolute error on the two-term approximation:

$$\left| \frac{\pi}{2} - C_1 - \delta C_1 \right| \le \frac{1}{2} \, \mathfrak{u} \left(\frac{\pi}{2} - C_1 \right) = 2^{\kappa_1' - M - 1} \, \mathfrak{u} \left(\frac{\pi}{2} \right) \tag{4}$$

and the following upper bound for δC_1 :

$$|\delta C_1| < \frac{\pi}{2} - C_1 + \frac{1}{2} \mathfrak{u} \left(\frac{\pi}{2} - C_1 \right)$$

$$< 2^{\kappa_1'} \mathfrak{u} \left(\frac{\pi}{2} \right) + 2^{\kappa_1' - M - 1} \mathfrak{u} \left(\frac{\pi}{2} \right) = 2^{\kappa_1'} (1 + 2^{-M - 1}) \mathfrak{u} \left(\frac{\pi}{2} \right)$$
(5)

This scheme gives a representation with a significand that has effectively $2M - \kappa'_1$ bits and is such that multiplying C_1 by an integer less than or equal to 2^{κ_1} is exact.

Three-Term Approximation

In this scheme we approximate $\frac{\pi}{2}$ as the sum of three floating-point numbers:

$$\frac{\pi}{2} \simeq C_2 + C_2' + \delta C_2$$

which are defined as:

$$\begin{cases} C_2 & \coloneqq \operatorname{Tr}\left(\kappa_2, \frac{\pi}{2}\right) \\ C_2' & \coloneqq \operatorname{Tr}\left(\kappa_2, \frac{\pi}{2} - C_2\right) \\ \delta C_2 & \coloneqq \left[\left[\frac{\pi}{2} - C_2 - C_2'\right]\right] \end{cases}$$

Equation (2) applied to the definition of C_2 yields:

$$2^{\kappa_2'-1} \, \mathfrak{u}\left(\frac{\pi}{2}\right) \le \frac{\pi}{2} - C_2 < 2^{\kappa_2'} \, \mathfrak{u}\left(\frac{\pi}{2}\right) \tag{6}$$

where $\kappa_2' \le \kappa_2$ accounts for any leading zeroes in the bits of $\frac{\pi}{2}$ that are being truncated. Accordingly equation (3) yields, for the unit of the last place:

$$\mathfrak{u}\left(\frac{\pi}{2} - C_2\right) = 2^{\kappa_2' - M} \mathfrak{u}\left(\frac{\pi}{2}\right)$$

Similarly, equation (2) applied to the definition of C'_2 yields:

$$2^{\kappa_2''-1} \mathfrak{u}\left(\frac{\pi}{2} - C_2\right) \le \frac{\pi}{2} - C_2 - C_2' < 2^{\kappa_2''} \mathfrak{u}\left(\frac{\pi}{2} - C_2\right)$$
$$2^{\kappa_2' + \kappa_2'' - M - 1} \mathfrak{u}\left(\frac{\pi}{2}\right) \le < 2^{\kappa_2' + \kappa_2'' - M} \mathfrak{u}\left(\frac{\pi}{2}\right)$$

where $\kappa_2'' \le \kappa_2$ accounts for any leading zeroes in the bits of $\frac{\pi}{2} - C_2$ that are being truncated. Note that normalization of the significand of $\frac{\pi}{2} - C_2$ effectively drops the zeroes at positions κ_2 to κ_2' and therefore the computation of C_2' applies to a significand aligned on position κ_2' .

It is straightforward to transform these inequalities using (6) to obtain bounds on C_2' :

$$2^{\kappa_2'} \left(\frac{1}{2} - 2^{\kappa_2'' - M}\right) \mathfrak{u}\left(\frac{\pi}{2}\right) < C_2' < 2^{\kappa_2'} (1 - 2^{\kappa_2'' - M - 1}) \mathfrak{u}\left(\frac{\pi}{2}\right)$$

Equation (3) applied to the definition of C'_2 yields, for the unit of the last place:

$$\begin{split} \mathfrak{u} \Big(\frac{\pi}{2} - C_2 - C_2' \Big) &= 2^{\kappa_2'' - M} \, \mathfrak{u} \Big(\frac{\pi}{2} - C_2 \Big) \\ &= 2^{\kappa_2' + \kappa_2'' - 2M} \, \mathfrak{u} \Big(\frac{\pi}{2} \Big) \end{split}$$

Noting that the absolute error on the rounding that appears in the definition of δC_2 is bounded by $\frac{1}{2} \mathfrak{u} \left(\frac{\pi}{2} - C_2 - C_2' \right)$, we obtain the absolute error on the three-term approximation:

$$\left|\frac{\pi}{2} - C_2 - C_2' - \delta C_2\right| \le \frac{1}{2} \, \mathfrak{u} \left(\frac{\pi}{2} - C_2 - C_2'\right) = 2^{\kappa_2' + \kappa_2'' - 2M - 1} \, \mathfrak{u} \left(\frac{\pi}{2}\right) \tag{7}$$

and the following upper bound for δC_2 :

$$|\delta C_2| < 2^{\kappa_2' + \kappa_2'' - M} (1 + 2^{-M-1}) \mathfrak{u}\left(\frac{\pi}{2}\right)$$
 (8)

This scheme gives a representation with a significand that has effectively $3M - \kappa_2' - \kappa_2''$ bits and is such that multiplying C_2 and C_2' by an integer less than or equal to 2^{κ_2} is exact.

Argument Reduction

Given an argument x, the purpose of argument reduction is to compute a pair of floating-point numbers $(\hat{x}, \delta \hat{x})$ such that:

$$\begin{cases} \hat{x} + \delta \hat{x} \cong x \pmod{\frac{\pi}{2}} \\ \hat{x} \text{ is approximately in } \left[-\frac{\pi}{4}, \frac{\pi}{4} \right] \\ |\delta \hat{x}| \leq \frac{1}{2} \mathfrak{u}(\hat{x}) \end{cases}$$

Argument Reduction for Small Angles

If
$$|x| < \left[\frac{\pi}{4}\right]$$
 then $\hat{x} = x$ and $\delta \hat{x} = 0$.

Argument Reduction Using the Two-Term Approximation

If $|x| \le 2^{\kappa_1} \left[\frac{\pi}{2} \right]$ we compute:

$$\begin{cases} n &= \left[\left[x \left[\frac{2}{\pi} \right] \right] \right] \\ y &= x - n C_1 \\ \delta y &= \left[n \delta C_1 \right] \right] \\ (\hat{x}, \delta \hat{x}) &= \text{TwoDifference}(y, \delta y) \end{cases}$$

The first thing to note is that $|n| \le 2^{\kappa_1}$. We have:

$$|x| \le 2^{\kappa_1} \left[\frac{\pi}{2} \right] = 2^{\kappa_1} \frac{\pi}{2} (1 + \delta_1)$$

and:

$$\|x\| \frac{2}{\pi} \| = x \frac{2}{\pi} (1 + \delta_2)(1 + \delta_3)$$
 (9)

from which we deduce the upper bound:

$$|n| \le \left[2^{\kappa_1} \frac{\pi}{2} (1 + \delta_1) \frac{2}{\pi} (1 + \delta_2) (1 + \delta_3) \right]$$

$$\le \left[2^{\kappa_1} (1 + \gamma_3) \right]$$

If $2^{\kappa_1}\gamma_3$ is small enough (less that 1/2), the rounding cannot cause n to exceed 2^{κ_1} . In practice we choose a relatively small value for κ_1 , so this condition is met.

Now if x is close to an odd multiple of $\frac{\pi}{4}$ it is possible for misrounding to happen. In the following analysis we assume that n > 0. The results are symmetrical if n < 0. There are two possible kinds of misrounding, with different bounds.

A misrounding of the first kind occurs if:

$$x < \left(n - \frac{1}{2}\right)\frac{\pi}{2}$$
 and $\left[x\left[\frac{2}{\pi}\right]\right] > n - \frac{1}{2}$

Using equation (9) we find that this misrounding is possible iff:

$$x > \frac{\pi}{2} \left(n - \frac{1}{2} \right) \frac{1}{(1 + \delta_2)(1 + \delta_3)} \ge \frac{\pi}{2} \left(n - \frac{1}{2} \right) \frac{1}{(1 + \gamma_2)}$$

In which case the computation of n results in:

$$n\frac{\pi}{2} - x < \frac{\pi}{4} \left(1 + \frac{\gamma_2}{1 + \gamma_2} (2n - 1) \right)$$

This bound tells us that the absolute value of the reduced angle may exceed $\frac{\pi}{4}$ by as much as:

$$\frac{\pi}{4} \frac{\gamma_2}{1 + \gamma_2} (2^{\kappa_1 + 1} - 1) \tag{10}$$

A misrounding of the second kind occurs if:

$$x > \left(n + \frac{1}{2}\right)\frac{\pi}{2}$$
 and $\left\|x\right\|\frac{2}{\pi}\right\| < n + \frac{1}{2}$

A derivation similar to the one above gives the following condition for this misrounding to be possible. Using equation (9):

$$x < \frac{\pi}{2} \left(n + \frac{1}{2} \right) \frac{1}{(1 + \delta_2)(1 + \delta_3)} \le \frac{\pi}{2} \left(n + \frac{1}{2} \right) (1 + \gamma_2)$$

from which we derive the bound:

$$x - n\frac{\pi}{2} < \frac{\pi}{4}(1 + \gamma_2(2n+1))$$

and thus the excess above $\frac{\pi}{4}$:

$$\frac{\pi}{4}\gamma_2(2^{\kappa_1+1}+1) \tag{11}$$

The bounds (10) and (11) need to be taken into account when building the accurate tables.

Using the bound on |n| and the fact that C_1 has κ_1 trailing zeroes, we see that the product n C_1 is exact. The subtraction x-n C_1 is exact by Sterbenz's Lemma. Finally, the last step performs an exact addition² using algorithm 4 of [HLBo8].

To compute the overall error on argument reduction³, first remember that, from equation (4), we have:

$$C_1 + \delta C_1 = \frac{\pi}{2} + \zeta$$
 with $|\zeta| \le 2^{\kappa'_1 - M - 1} \mathfrak{u}\left(\frac{\pi}{2}\right)$

The error computation proceeds as follows:

$$y - \delta y = x - n C_1 - n \delta C_1 (1 + \delta_4)$$
$$= x - n(C_1 + \delta C_1) - n \delta C_1 \delta_4$$
$$= x - n \frac{\pi}{2} - n(\zeta + \delta C_1 \delta_4)$$

from which we deduce an upper bound on the absolute error of the reduction:

$$\begin{split} \left| y - \delta y - \left(x - n \frac{\pi}{2} \right) \right| &\leq 2^{\kappa_1} 2^{\kappa_1'} (2^{-M-1} + 2^{-M} + 2^{-2M-1}) \, \mathfrak{u} \left(\frac{\pi}{2} \right) \\ &= 2^{\kappa_1 + \kappa_1' - M} \left(\frac{3}{2} + 2^{-M-1} \right) \mathfrak{u} \left(\frac{\pi}{2} \right) \\ &< 2^{\kappa_1 + \kappa_1' - M + 1} \, \mathfrak{u} \left(\frac{\pi}{2} \right) \end{split}$$

where we have used the upper bound for δC_1 given by equation (5).

In the computation of the trigonometric functions, we need $\hat{x} + \delta \hat{x}$ to provide enough accuracy that the final result is correctly rounded most of the time, and that

$$|\delta y| \ge n \ 2^{\kappa_1'-1} \operatorname{u}\left(\frac{\pi}{2}\right) \ge 2^{\kappa_1'+M-2} \operatorname{u}\left(\frac{\pi}{2}\right) \operatorname{u}(n)$$

where we used the bound given by equation (1). Now the computation of n can result in a value that is either in the same binade or in the binade below that of x. Therefore $\mathfrak{u}(n) \geq \frac{1}{2} \mathfrak{u}(x)$ and the above inequality becomes:

$$|\delta y| \ge 2^{\kappa_1' + M - 3} \mathfrak{u}\left(\frac{\pi}{2}\right) \mathfrak{u}(x)$$

plugging $u\left(\frac{\pi}{2}\right) = 2^{1-M}$ we find:

$$|\delta y| \ge 2^{\kappa_1' - 2} \, \mathfrak{u}(x)$$

Therefore, as long as $\kappa'_1 > 2$, there exist arguments x for which $|\delta y| > |y|$.

³Note that this error analysis is correct even in the face of misrounding. Misrounding can combine with the argument reduction error, though, to cause $|y - \delta y|$ to move farther above $\frac{\pi}{4}$

²The more efficient QuickTwoDifference is not usable here. First, note that |y| is equal to u(x) if we take x to be the successor or the predecessor of nC_1 for any n. Ignoring rounding errors we have:

any case of incorrect rounding may be detected. The above error bound shows that, if \hat{x} is very small (i.e., if x is very close to a multiple of $\frac{\pi}{2}$), the two-term approximation may not provide enough correct bits. Formally, say that we want to have $M + \kappa_3$ correct bits in the mantissa of $\hat{x} + \delta \hat{x}$. The error must be less than $2^{-\kappa_3}$ half-units of the last place of the result:

$$2^{\kappa_1 + \kappa_1' - M + 1} \, \mathfrak{u}\left(\frac{\pi}{2}\right) \le 2^{-\kappa_3 - 1} |\mathfrak{u}(\hat{x})| \le 2^{-\kappa_3 - M} |\hat{x}|$$

which leads to the following condition on the reduced angle:

$$|\hat{x}| \ge 2^{\kappa_1 + \kappa_1' + \kappa_3 + 1} \, \mathfrak{u}\left(\frac{\pi}{2}\right) = 2^{\kappa_1 + \kappa_1' + \kappa_3 - M + 2}$$

The rest of the implementation assumes that $\kappa_3 = 18$ to achieve correct rounding most of the time and detect cases of dangerous rounding. If we choose $\kappa_1 = 8$ we find that $\kappa_1' = 5$ (because there are three consecutive zeroes at this location in the significand of $\frac{\pi}{2}$) and the desired accuracy is obtained as long as $|\hat{x}| \ge 2^{-20} \simeq 9.5 \times 10^{-7}$.

Argument Reduction Using the Three-Term Approximation

If $|x| \le 2^{\kappa_2} \left[\frac{\pi}{2} \right]$ we compute:

$$\begin{cases} n &= \left[\left[x \left[\frac{2}{\pi} \right] \right] \right] \\ y &= x - n C_2 \\ y' &= n C'_2 \\ \delta y &= \left[n \delta C_2 \right] \\ (z, \delta z) &= \text{QuickTwoSum}(y', \delta y) \\ (\hat{x}, \delta \hat{x}) &= \text{LongSub}(y, (z, \delta z)) \end{cases}$$

The products n C_2 and n C_2' are exact thanks to the κ_2 trailing zeroes of C_2 and C_2' . The subtraction x-n C_2 is exact by Sterbenz's Lemma. QuickTwoSum performs an exact addition using algorithm 3 of [HLBo8]; it is usable in this case because clearly $|\delta y| < |y'|$. LongSub is the obvious adaptation of the algorithm LongAdd presented in section 5 of [Lin81], which implements precise (but not exact) double-precision arithmetic.

It is straightforward to show, like we did in the preceding section, that:

$$|n| \leq [2^{\kappa_2}(1+\gamma_3)]$$

and therefore that $|n| \le 2^{\kappa_2}$ as long as $2^{\kappa_2} \gamma_3 < 1/2$. Similarly, the misrounding bounds (10) and (11) are applicable with κ_2 replacing κ_1 .

To compute the overall error on argument reduction, first remember that, from equation (7), we have:

$$C_2 + C_2' + \delta C_2 = \frac{\pi}{2} + \zeta_1 \quad \text{with} \quad |\zeta_1| \le 2^{\kappa_2' + \kappa_2'' - 2M - 1} \, \mathfrak{u}\left(\frac{\pi}{2}\right)$$

Let ζ_2 be the relative error introduced by LongAdd. Table 1 of [Lin81] indicates that $|\zeta_2| < 2^{2-2M}$. The error computation proceeds as follows:

$$\begin{split} y - y' - \delta y &= (x - n \ C_2 - n \ C_2' - n \ \delta C_2 (1 + \delta_4))(1 + \zeta_2) \\ &= \left(x - n \frac{\pi}{2} - n(\zeta_1 + \delta C_2 \ \delta_4)\right)(1 + \zeta_2) \\ &= x - n \frac{\pi}{2} - n(\zeta_1 + \delta C_2 \ \delta_4)(1 + \zeta_2) + \left(x - n \frac{\pi}{2}\right)\zeta_2 \end{split}$$

from which we deduce an upper bound on the absolute error of the reduction, noting that $\left|x-n\frac{\pi}{2}\right| \leq \frac{\pi}{4}$:

$$\begin{split} \left| y - y' - \delta y - \left(x - n \frac{\pi}{2} \right) \right| \\ & \leq 2^{\kappa_2 + \kappa_2'' + \kappa_2''} (2^{-2M - 1} + 2^{-2M} + 2^{-3M - 1}) (1 + 2^{2 - 2M}) \, \mathfrak{u} \left(\frac{\pi}{2} \right) + 2^{2 - 2M} \frac{\pi}{4} \\ & = 2^{\kappa_2 + \kappa_2' + \kappa_2'' - 2M} \left(\frac{3}{2} + 2^{-M - 1} \right) (1 + 2^{2 - 2M}) \, \mathfrak{u} \left(\frac{\pi}{2} \right) + 2^{-2M} \, \pi \\ & < 2^{\kappa_2 + \kappa_2' + \kappa_2'' - 2M + 1} \, \mathfrak{u} \left(\frac{\pi}{2} \right) + 2^{-2M} \, \pi \end{split}$$

A sufficient condition for the reduction to guarantee κ_3 extra bits of accuracy is for this error to be less than $2^{-\kappa_3-1}|\mathfrak{u}(\hat{x})|$ which itself is less than $2^{-\kappa_3-M}|\hat{x}|$. Therefore we want:

$$|\hat{x}| \ge 2^{\kappa_3 - M} \left(2^{\kappa_2 + \kappa_2' + \kappa_2'' + 1} \mathfrak{u} \left(\frac{\pi}{2} \right) + \pi \right)$$
$$= 2^{\kappa_3 - M} \left(2^{\kappa_2 + \kappa_2' + \kappa_2'' - M + 2} + \pi \right)$$

and it is therefore sufficient to have:

$$|\hat{x}| > 2^{\kappa_3 - M} (2^{\kappa_2 + \kappa_2' + \kappa_2'' - M + 2} + 4)$$

If we choose $\kappa_3=18$ as above, and $\kappa_2=18$ we find that $\kappa_2'=14$ and $\kappa_2''=15$. Therefore, the desired accuracy is obtained as long as $|\hat{x}| \geq 65 \times 2^{-39} \simeq 1.2 \times 10^{-10}$.

Fallback

If any of the conditions above is not met, we fall back on the CORE-MATH implementation.

Accurate Tables and Their Generation

Computation of the Functions

Sin

Near Zero

For \hat{x} near zero we evaluate:

$$\widehat{x^{2}} = [[\hat{x}^{2}]] = \hat{x}^{2}(1 + \delta_{1})$$

$$\widehat{x^{3}} = [[\hat{x} \hat{x^{2}}]] = \hat{x}^{3}(1 + \delta_{1})(1 + \delta_{2})$$

$$\widehat{p} = [[ax^{2} + b]] = (a\hat{x}^{2}(1 + \delta_{1}) + b)(1 + \delta_{3})$$

$$s(x) := \hat{x} + [[[x^{3}\hat{p}]]] + \delta \hat{x}]$$

$$= \hat{x} + (\hat{x}^{3}(1 + \delta_{1})(1 + \delta_{2})(a\hat{x}^{2}(1 + \delta_{1}) + b)(1 + \delta_{3})(1 + \delta_{4}) + \delta \hat{x})(1 + \delta_{5})$$

$$= \hat{x} + a\hat{x}^{3}(1 + \theta_{5}) + b\hat{x}^{5}(1 + \theta_{4}) + \delta \hat{x}(1 + \delta_{5})$$
